

Revision of the Flexible Pavement Design Method Phase 3

Industry feedback – 17th RPF

14 May 2009

H L Theyse

P_m^c

ME-design model for unbound material

- Components
 - Resilient response - SAPDM/B-1a
 - Resilient modulus (stiffness)
 - Poisson's ratio
 - Yield strength or shear strength - SAPDM/D-2
 - Damage model - SAPDM/D-2
 - Permanent deformation - plastic strain
- Preliminary model development based on available data

P_m^c

ME-design model for unbound material

- Models complicated
- Relate model parameters to basic engineering parameters
 - Grading
 - Atterberg indicators
 - Density
 - Moisture content (saturation)
- Hide complexity behind engineering interface

P_m^c

Project SAPDM/B-1a

Resilient response modelling for unbound material

P_m^c

Planned tasks – SAPDM/B-1a

Task	Activity	Deliverable number
Density, saturation and stress-dependent resilient modulus (chord modulus) models for unbound granular material (1)	Refine model formulation (a)	B-1a/1(a)
	Models for realistic density estimates (b)	B-1a/1(b)
	Validation of SA model moisture sensitivity (c)	B-1a/1(c)
Density, saturation and stress-dependent tangent modulus models for unbound granular material (2)	Model formulation and calibration (a)	B-1a/1(b)
Predictive resilient modulus models for unbound granular material and material modelling related to project SAMDM/B-2 [4(a)]		B-1a/4(a)

Resilient modulus model refinement

■ Objectives

- Rectify model formulation and include significant variables
- Ensure model satisfies statistical requirements for regression
- Explore development of predictive model for design
- Provide guidance on additional work

P_m^c

Current model: Uzan

$$M_r = p_{atm} 10^{K_0} \left(\frac{\theta'}{p_{atm}} \right)^{K_1} \left(\frac{\sigma_d}{p_{atm}} \right)^{K_2}$$

Problems

- Does not include density and saturation
- Does not satisfy statistical requirements

1st alternative: SR-model for individual materials

$$M_r = p_{atm} 10^{K_0} VD^{K_{VD}} S^{K_S} \left(\frac{\sigma'_3}{p_{atm}} \right)^{K_C} \left(\frac{\sigma'_1}{\sigma_1^y} \right)^{K_{SR}}$$

Stress Ratio Model

Stress ratio model

Design model: SR-model for combined materials

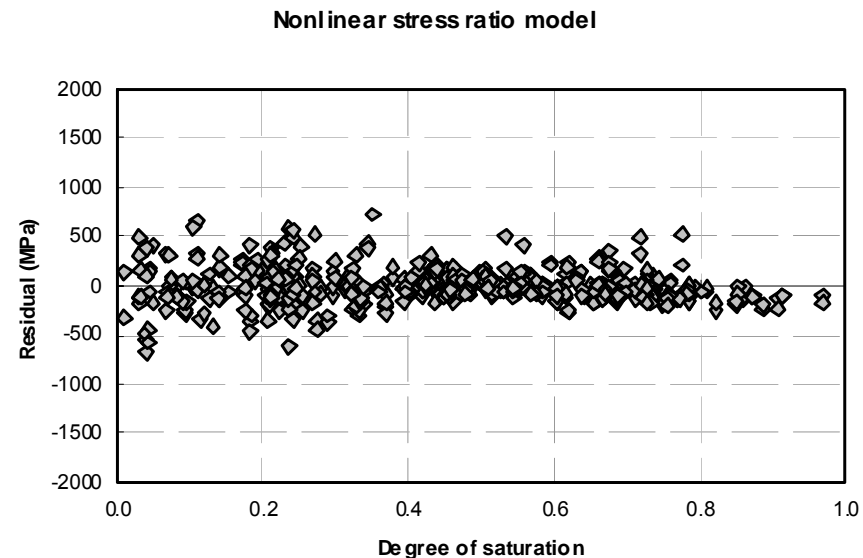

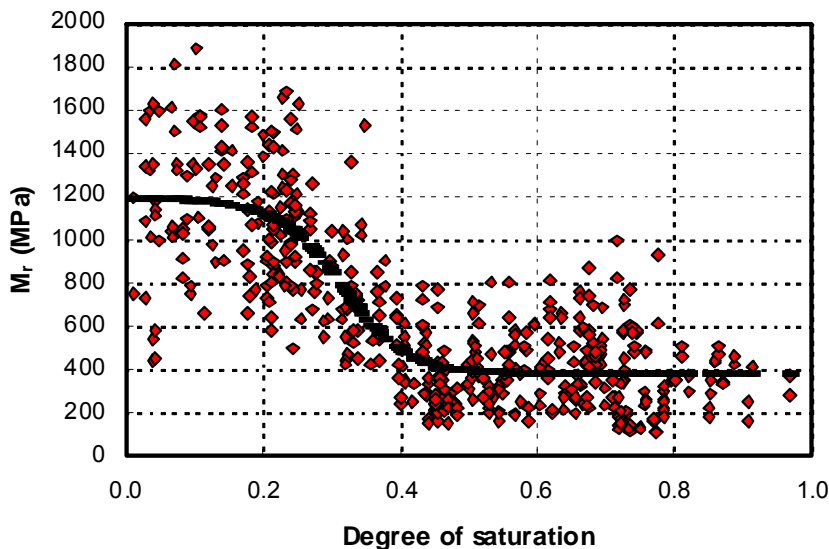

Problems

- Model over estimates stiffness at low saturation

2nd alternative: NLSR-model or Theyse Mr model

$$M_r = p_{atm} K_0 VD^{K_{VD}} \left\{ \frac{\exp[d(S-s)] + 1}{\frac{1}{b} + \frac{1}{a} \exp[d(S-s)]} \right\} \left(\frac{\sigma'_3}{p_{atm}} \right)^{K_C} \left(\frac{\sigma'_1}{\sigma_1^y} \right)^{K_{SR}}$$

Aspects of model calibration

- Calibration - extreme caution
 - Model for all materials combined
 - Explains inter-material variation but not intra-material variation
 - Crushed stone
 - Single model calibrated without material bias
 - Crushed gravel
 - Calibrated for one material
 - Natural gravel
 - No single saturation-stiffness relationship

P_m^c

Aspects of design application

- Model formulated in terms of effective stress - suction pressure estimates required
 - SAPDM/D-2 predictive models available
- Accurate yield strength estimates required
 - SAPDM/D-2
- Formulation appears complicated but model reduces to stress-stiffening, stress-softening model for given density and saturation levels

$$M_r = p_{atm} K_0 VD^{K_{VD}} \left\{ \frac{\exp[d(S-s)] + 1}{\frac{1}{b} + \frac{1}{a} \exp[d(S-s)]} \right\} \left(\frac{\sigma'_3}{p_{atm}} \right)^{K_C} \left(\frac{\sigma'_1}{\sigma_1^y} \right)^{K_{SR}}$$

P_m^c

Aspects of design application (continued)

- Density and saturation terms included in pre-processing
- Stress-dependent terms require feedback from continuum mechanics model and an iterative solution
 - ELSYM5 becomes a bit more complicated, more like ELSYM50
- Implementation in primary pavement response model (SAPDM/C-3)
 - Stress-dependent Poisson's ratio model, Bonaquist and Witczak (1997)
 - NLSR resilient modulus model

P_m^c

Future work under project B-1a

- Focus on moisture sensitivity of natural gravel material, test at
 - 10 % saturation
 - 20 - 25 % saturation
 - 35 - 40 % saturation
 - 80 % saturation
- Test additional crushed gravel material
- Assess prediction accuracy
 - data other than calibration data set

P_m^c

Project SAPDM/D-2

Damage modelling for unbound material

P_m^c

Planned tasks

Task	Activity	Deliverable number
Permanent deformation damage models for pavement subgrades (1)	Process W-Cape HVS data (a)	D-2/1(b)
	Calibrate S-N subgrade PD model (b)	
	Calibrate continuous model for recursive analysis (c)	D-2/1(c)
Yield strength models for unbound granular material (2)	Assess NCHRP SWCC predictive model (a)	D-2/2(a)
	SWCC predictive model for SA material (b)	D-2/2(b)
	Calibrate predictive yield strength model (c)	D-2/2(c)
Plastic strain damage models for unbound material (3)	Calibrate S-N type PS model for natural gravel (a)	D-2/3(a)
	Calibrate continuous PS model for recursive analysis (b)	D-2/3(b)

Yield strength of unbound material

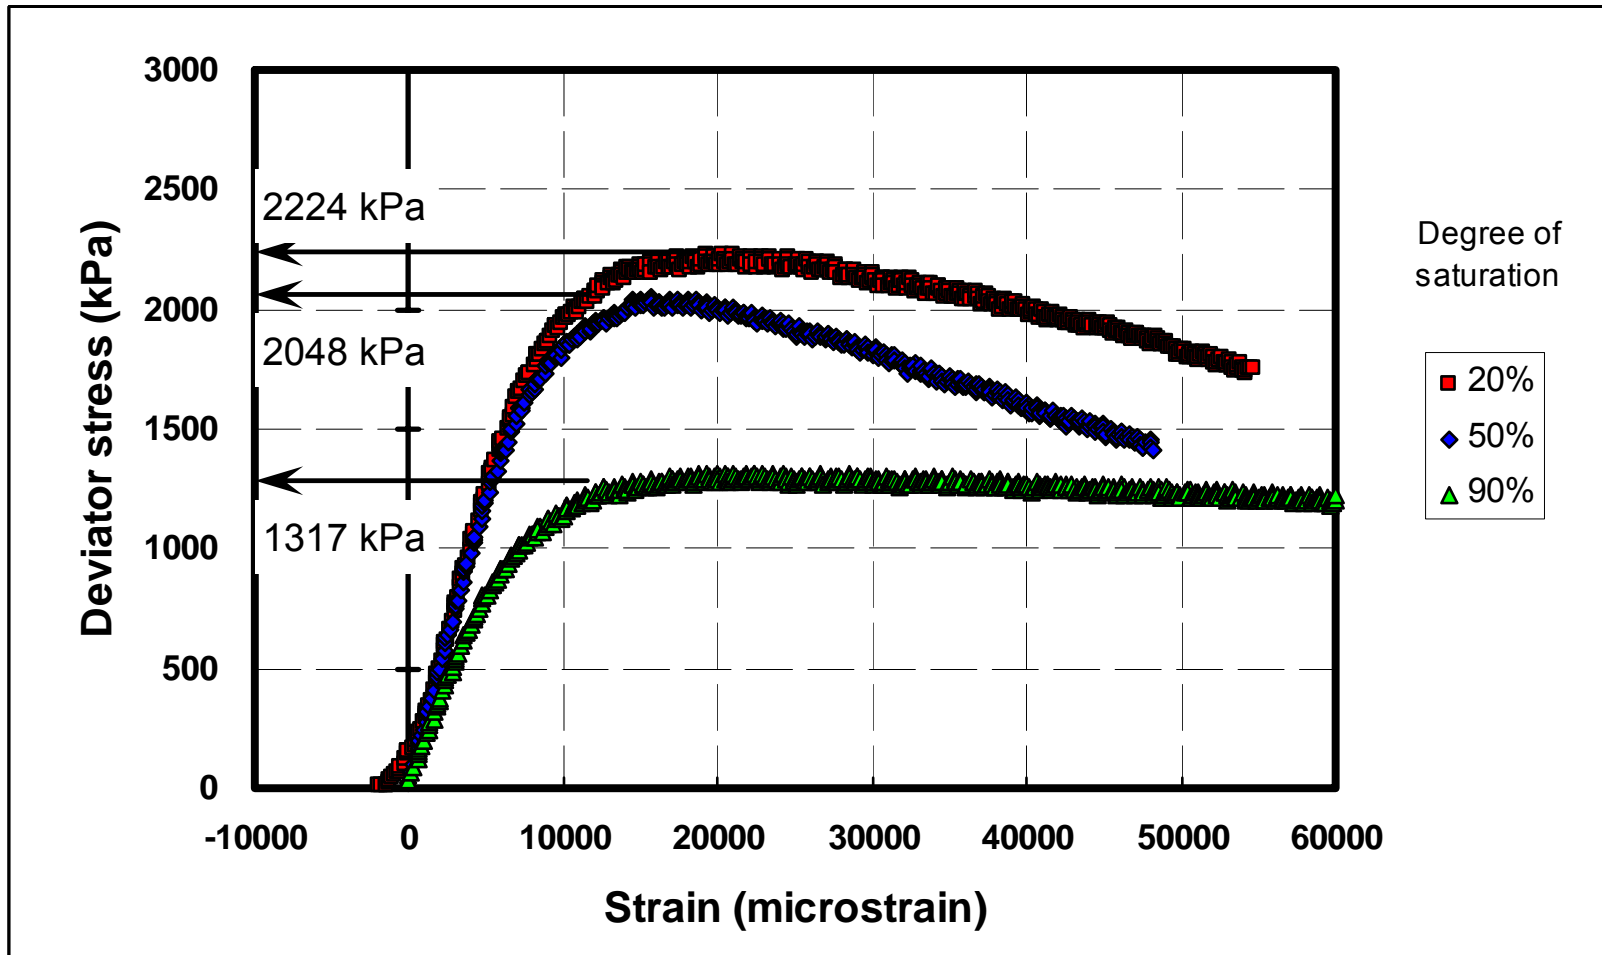

- All aspects of unbound material behaviour affected by yield strength
 - Resilient modulus and Poisson's ratio affected by stress ratio
 - Yield strength in stress ratio
 - Plastic strain related to stress ratio
 - yield strength in stress ratio
- Suction pressure affects
 - Effective stress
 - Yield strength

$$P_m^c$$

Yield strength of partially saturated, unbound granular material

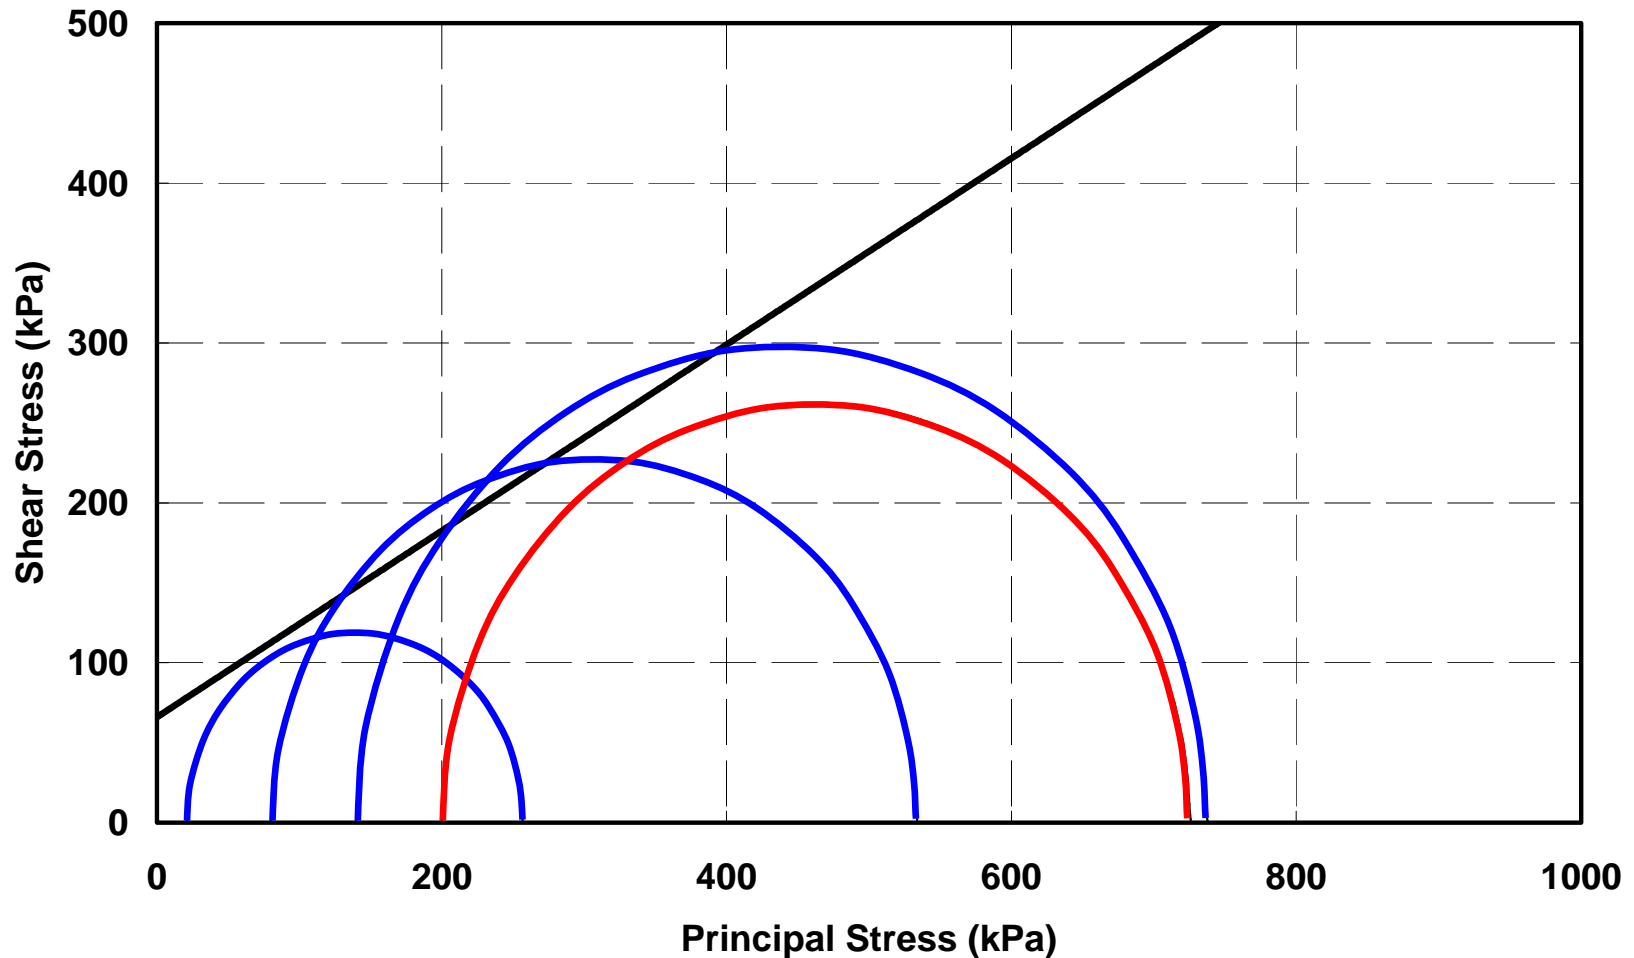

Yield strength of partially saturated, unbound granular material

Yield strength of partially saturated, unbound granular material

Yield strength of partially saturated, unbound granular material

Yield strength of partially saturated, unbound granular material

$$\sigma_1^y = \frac{e^{aVD}}{e^{bS}} (\sigma_3 + p_{suc})^c - p_{suc}$$

$$= \frac{e^{aVD}}{e^{bS}} \left(\sigma_3 + \frac{\rho S}{e^{\omega S / VD}} \right)^c - \frac{\rho S}{e^{\omega S / VD}}$$

Yield Strength Model with Suction Pressure Shale base (P10-2)

STEP 1: Suction pressure model

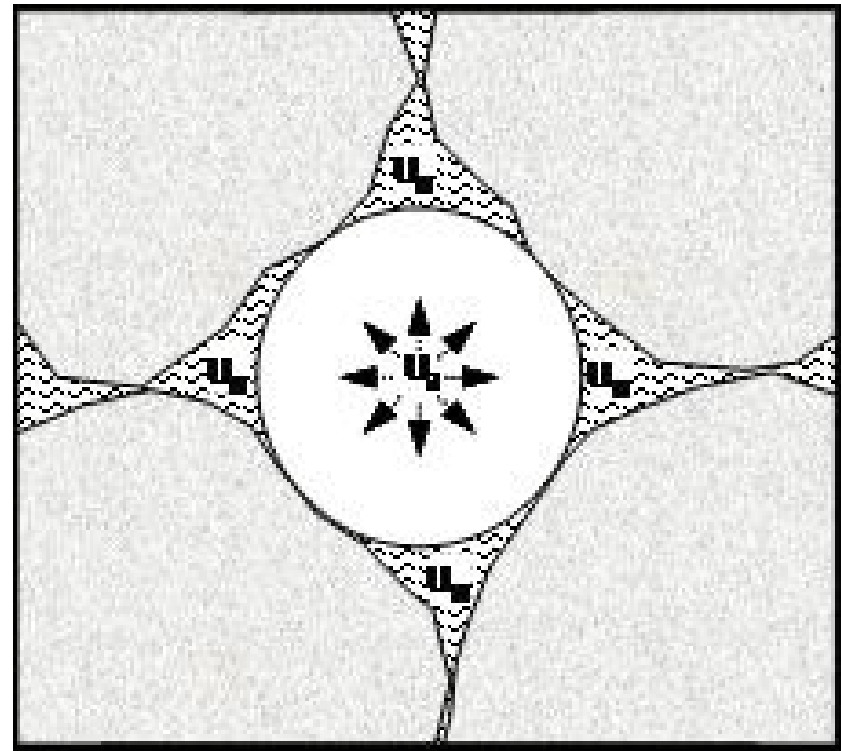

- Objective
 - Explore the development of predictive SWCCs for SA unbound materials
 - SWCC → Matric suction → suction pressure
 - Options
 - NCHRP 1-37a
 - Heath
 - Theyse

P_m^c

Suction pressure, matric suction, SWCC?

$$\text{matric suction} = (u_a - u_w)$$

- Matric suction
 - Measure of how easy it is to expel water from material
- SWCC
 - Relationship between matric suction and saturation

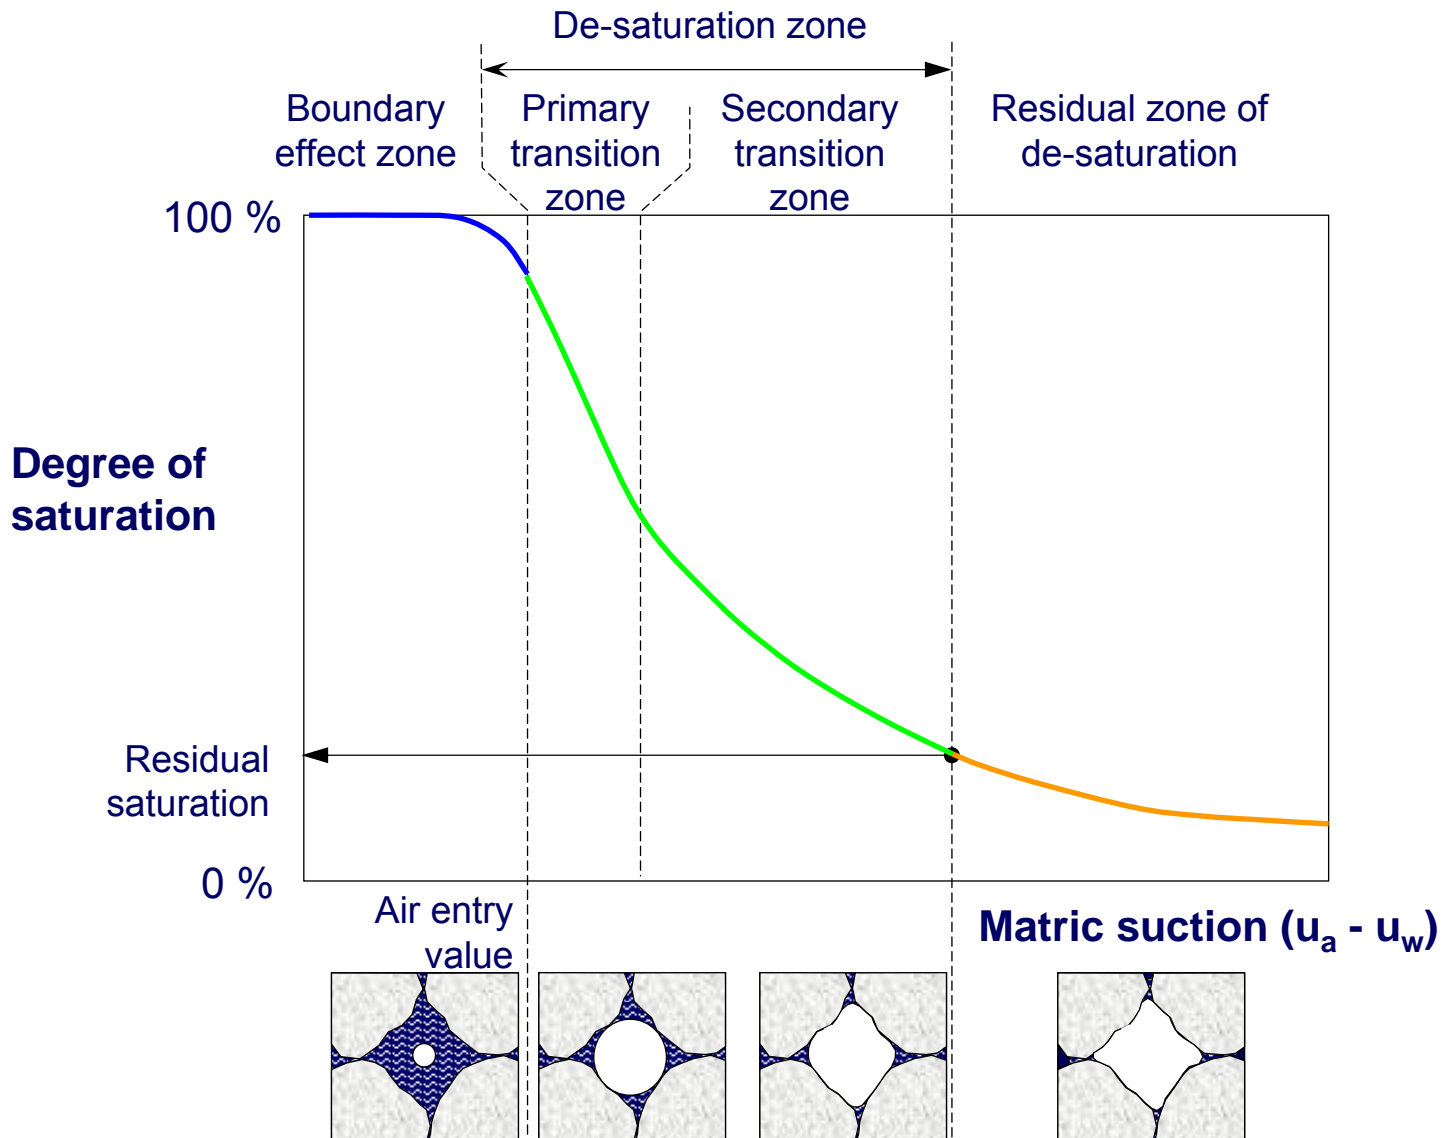

Soil-water characteristic curve – pressure plate equipment

$$P_m^c$$

Soil-Water characteristic curve

Matrix suction and effective stress

- Bishop
 - Suction pressure = Bishop parameter x matric suction
- Heath
 - Suction pressure \cong Saturation x matric suction

$$p_{suc} = S (u_a - u_w)$$

**Internal
stress**

Soil suction

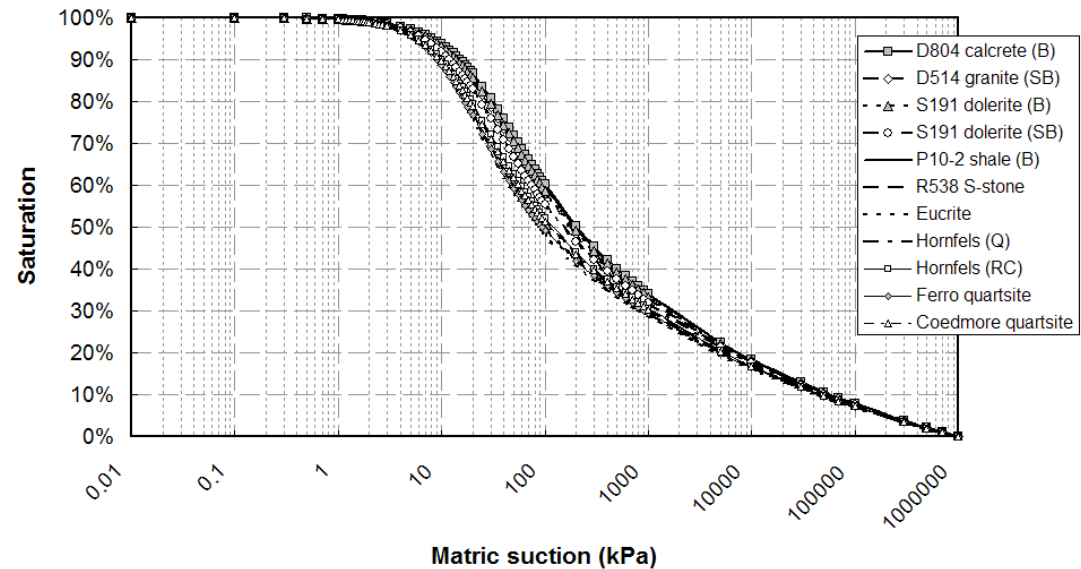

Option 1: NCHRP 1-37a SWCCs

Non-plastic material

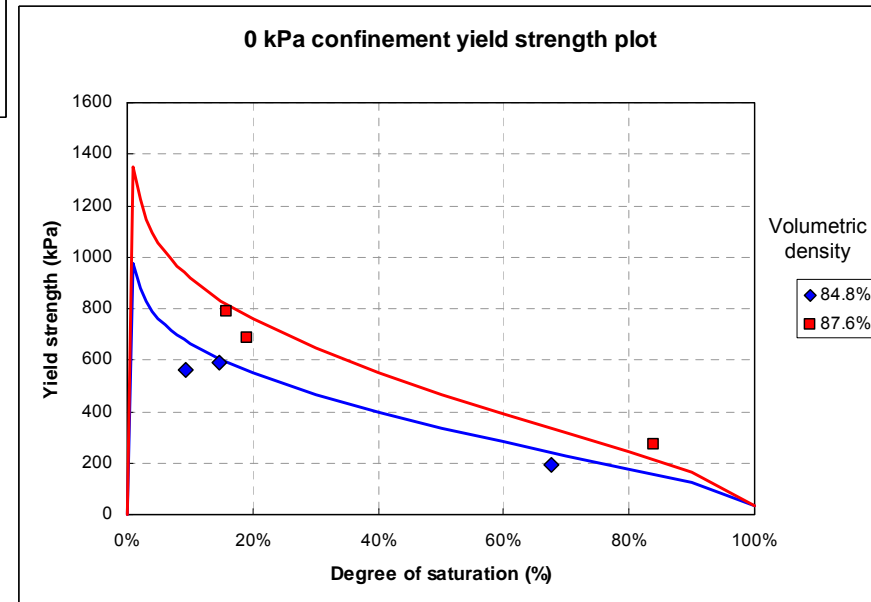

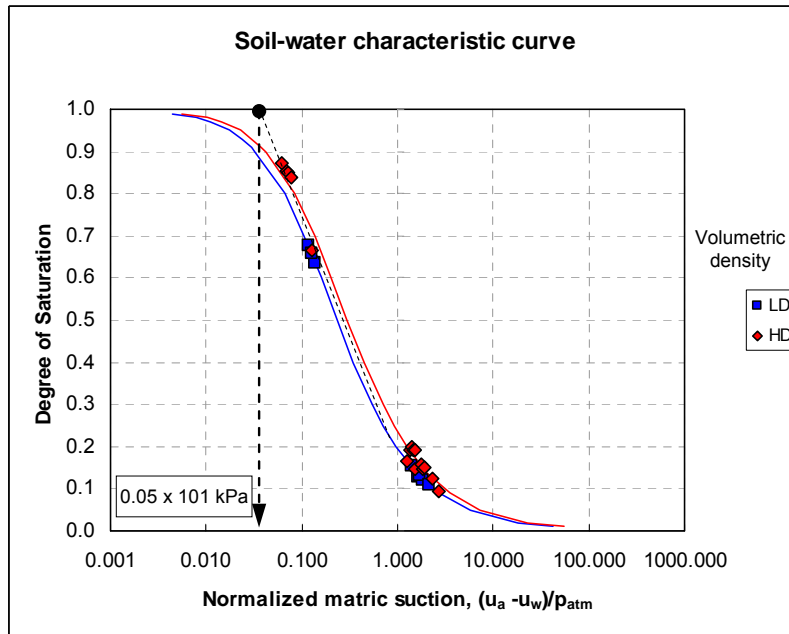

Plastic material

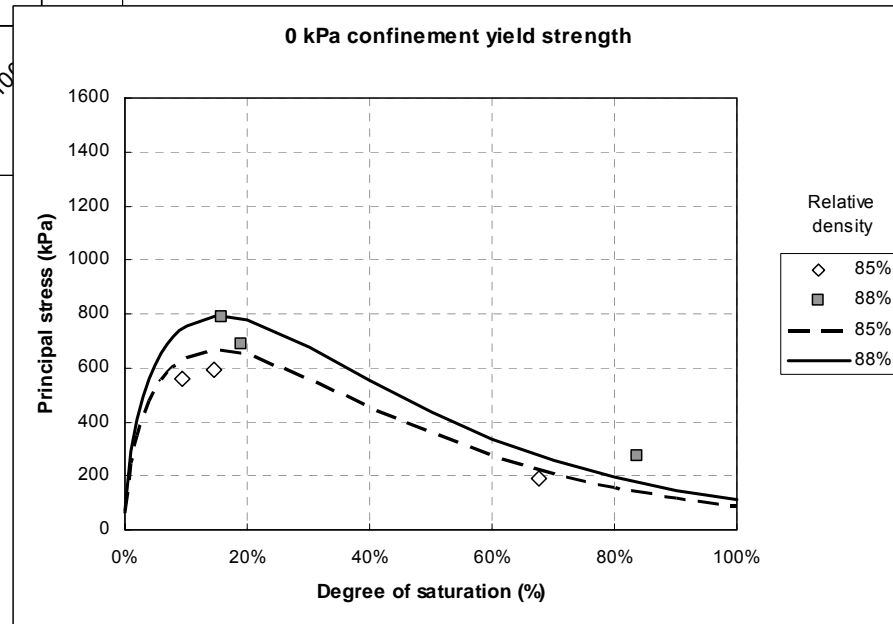

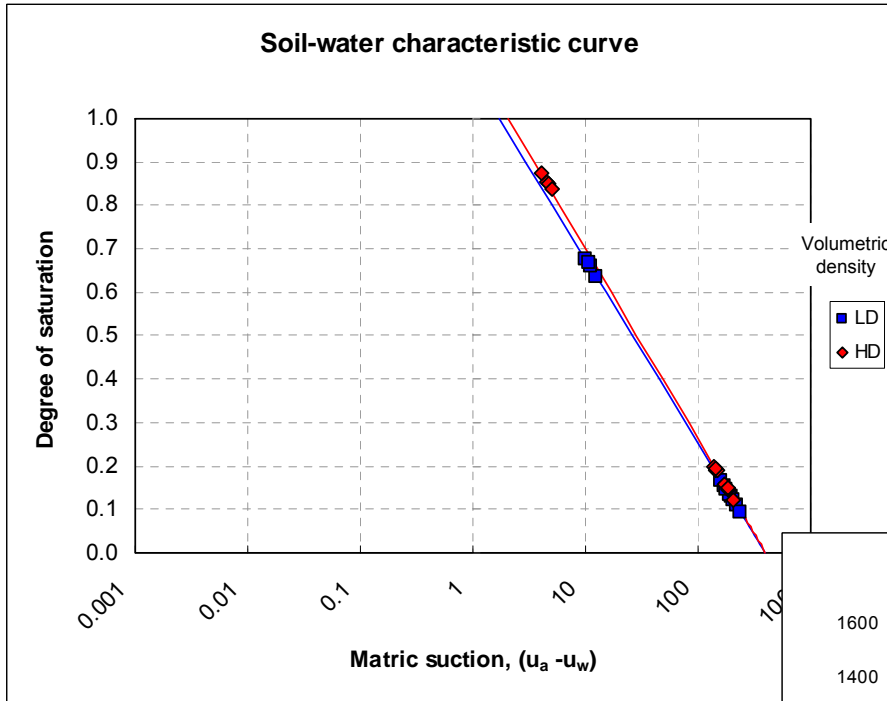

Matric suction

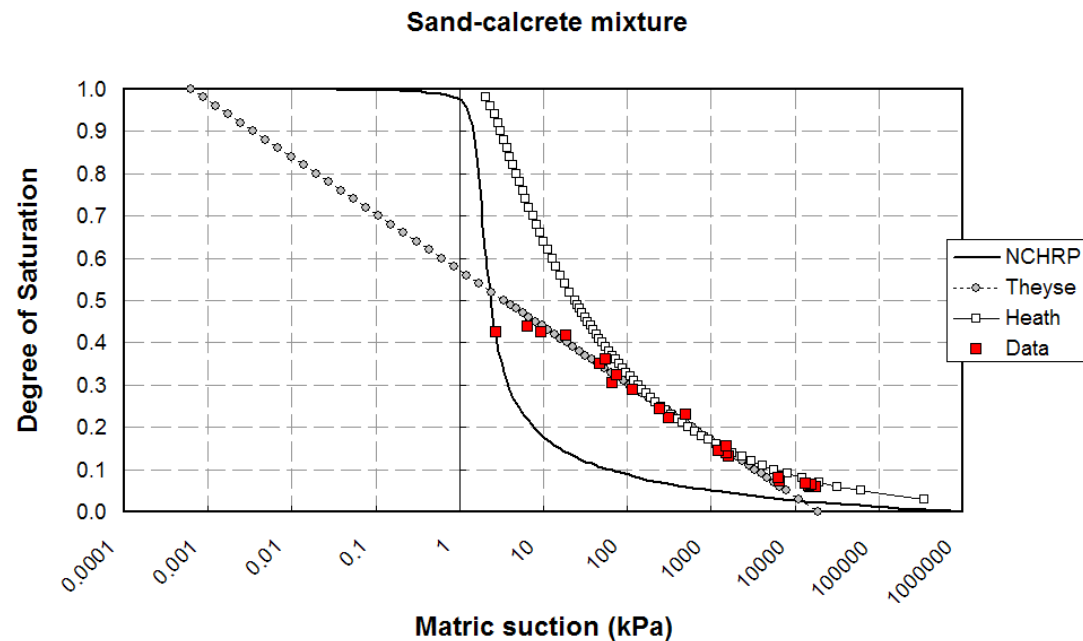

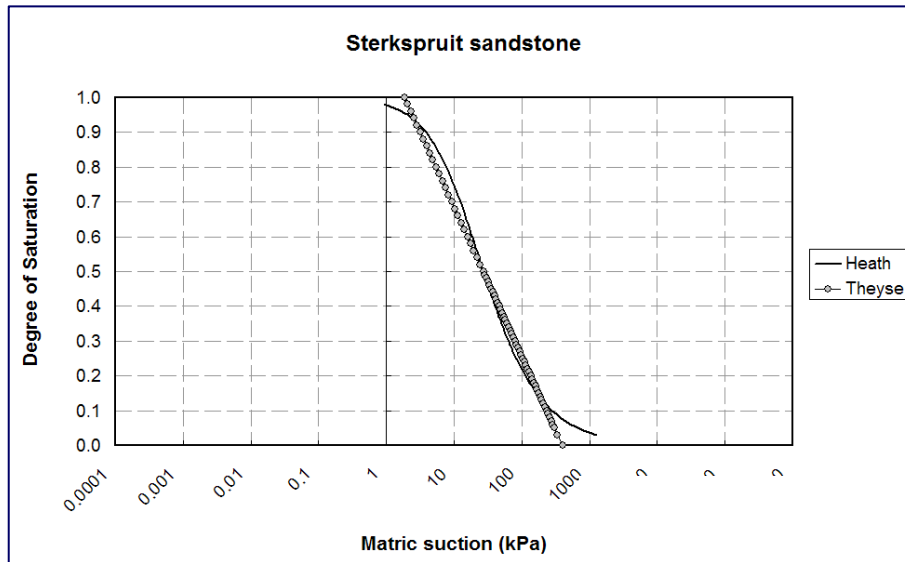

Option 2: Heath SWCC from suction pressure model

Option 3: Theyse SWCC from suction pressure model

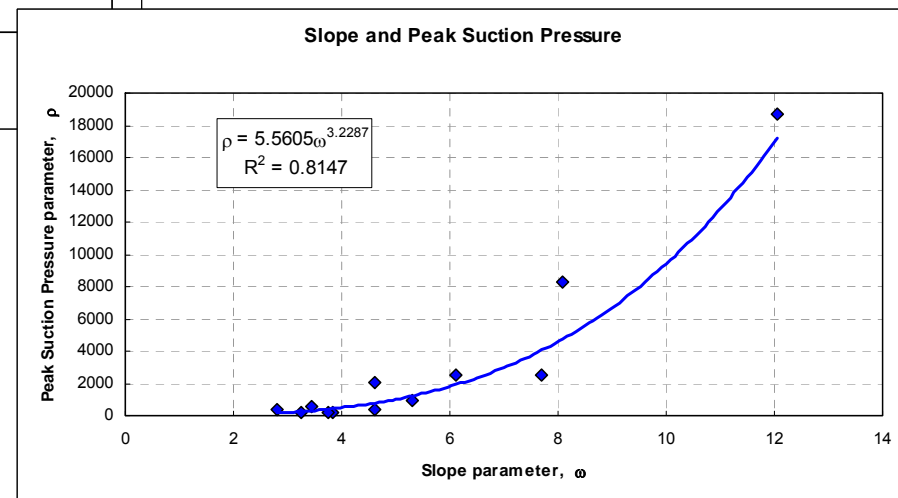

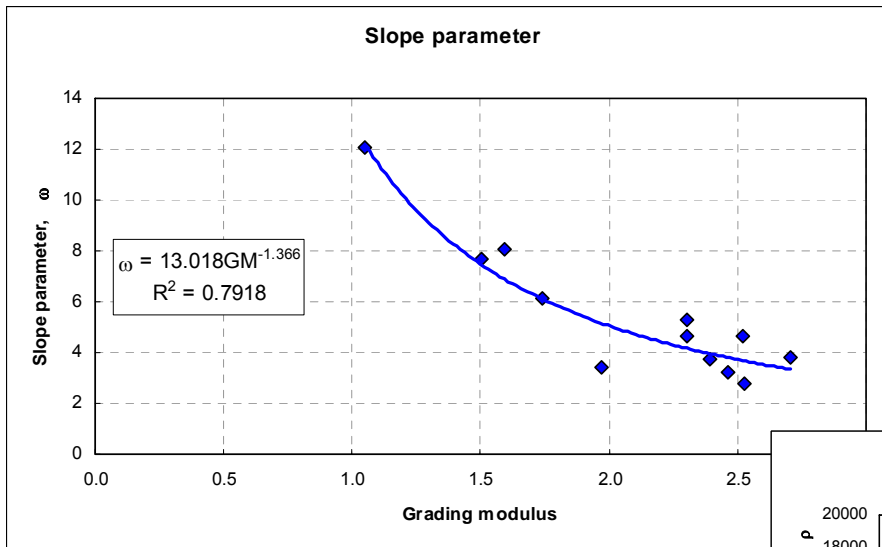

Heath - Theyse comparison

Predictive model development

$$P_{suc} = \frac{\rho S}{e^{\omega S / VD}}$$

How does the predictive P_{suc} model affect ability to model yield strength?

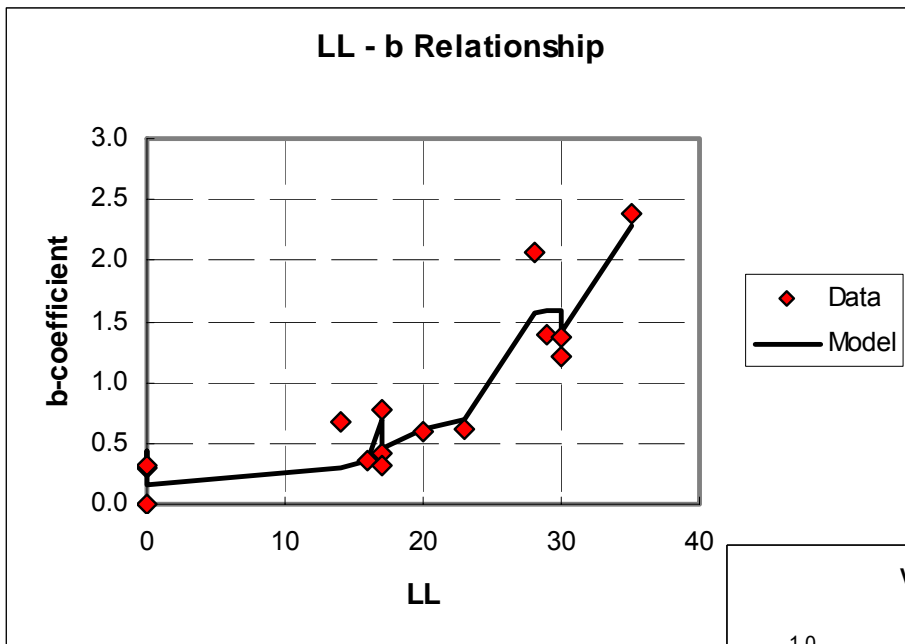

STEP 2: General yield strength model

- Objective
 - Explore the relationship between engineering parameters and yield strength model coefficients
 - Develop a general (predictive) yield strength model

P_m^c

General yield strength model

General yield strength model – calibration data

Crushed stone

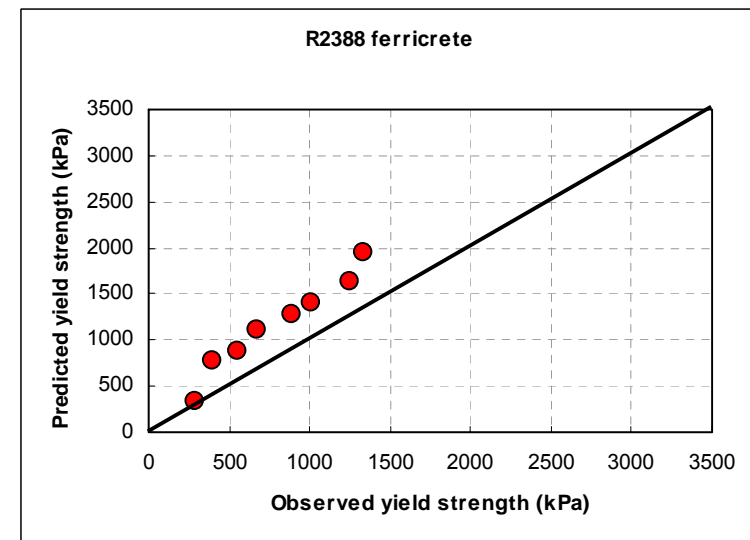

Natural gravel

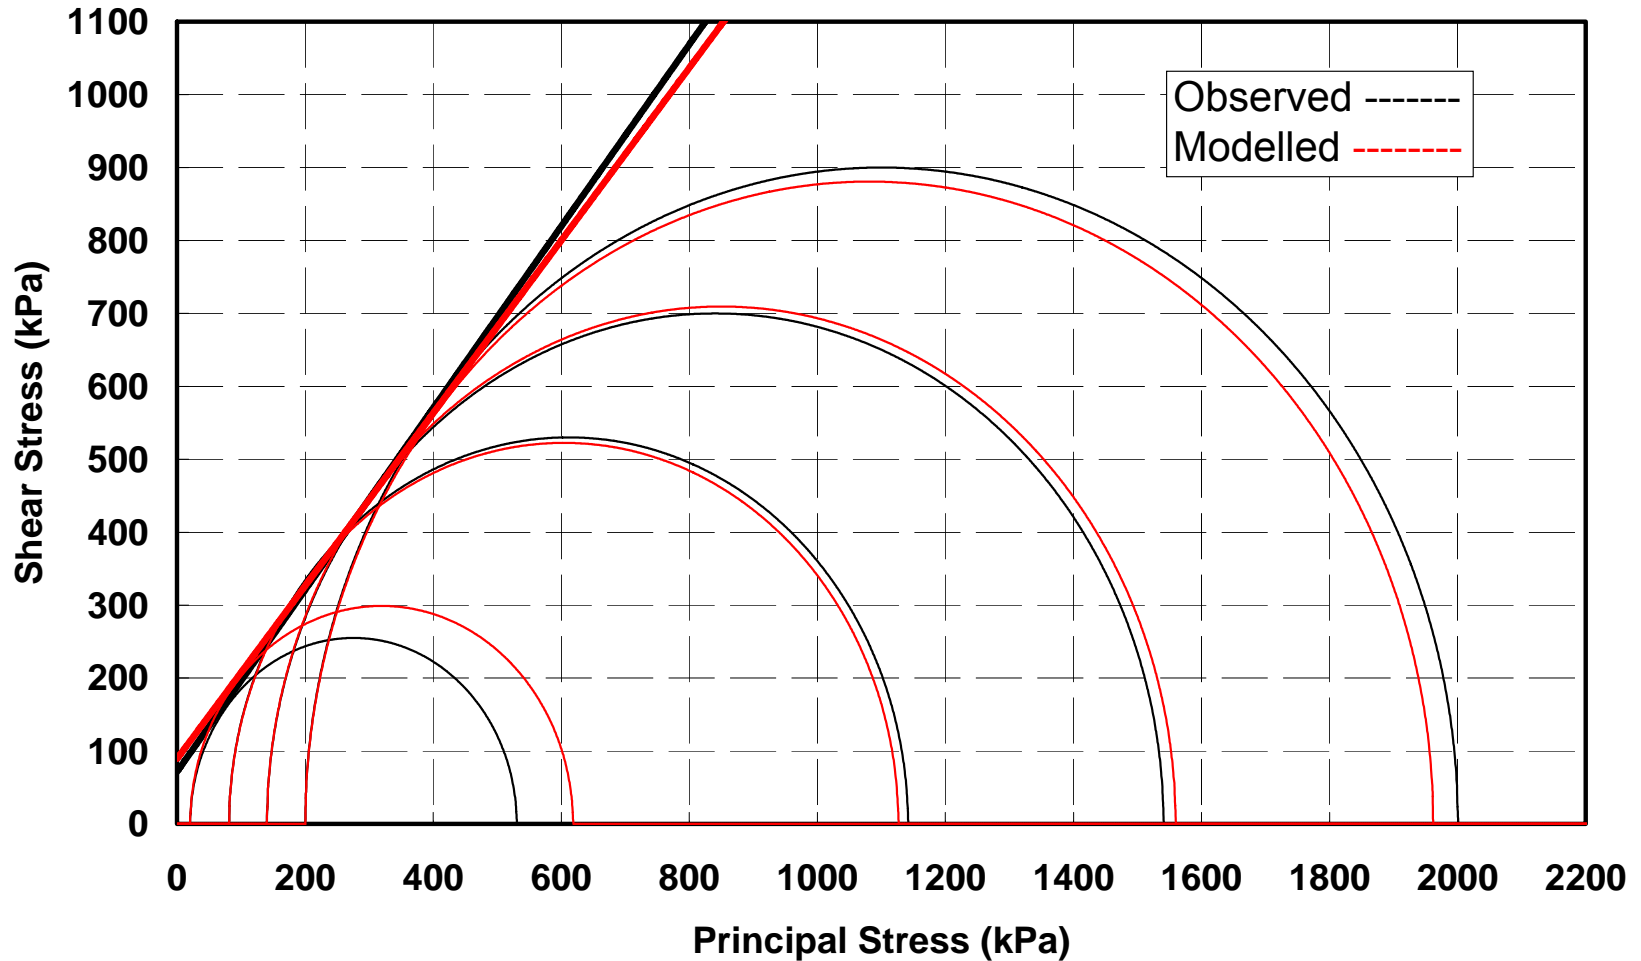

General yield strength model – validation data

Natural gravel

Crushed stone

General yield strength model – application

Closure

- Resilient response modelling
 - Correlation between independent variables eliminated
 - Density and saturation introduced in model
 - Highly significant variables
 - Single model for crushed stone
 - Use for design
 - Moisture content is the primary independent variable for natural gravel
 - Further testing required to relate effect of MC to engineering parameters

P_m^c

Closure

■ Yield strength

- Suction pressure and effective stress introduced in model
- General predictive model developed
 - Grading modulus and -0.075 mm fraction
 - LL and BLS
 - Replace C and ϕ table in current SAMDM
 - Seasonal MC variation
 - Construction related spatial density variation
- Primary independent variables
 - Density
 - Saturation
 - Confinement

P_m^c
